PATTERN OF PRIMARY PULMONARY MALIGANCIES IN CENTRAL PUNJAB

M. RIAZ HUSSAIN, SAEED A. KHAN, NASEER A. CHAUDHRY, M. ASHRAF AND M. TAYYIB
Departments of Pathology, PGMI, Gulab Devi Chest Hospital, University of Health Sciences, Lahore

Three hundred patients of primary malignancies of the lung from Gulab Devi Chest Hospital and other hospitals of Lahore were studied. The history of the patients and their clinical findings were recorded. The sections of the tissues were stained with haematoxylin and eosin whereas all large cell carcinomas were stained with Alcian Blue-Periodic Acid-Schiff (AB-PAS) stain. There were 255 males and 45 females with a male to female ration of 5.7:1. the age ranged from 10-90 years with a mean age of 54.17± 3.46 years. Different tumours were significantly more (p<0.001) in males than in females. The mean age in squamous cell carcinoma cases was significantly high (P<0.001) as compared to adenocarcinoma. Small cell carcinoma cases had significantly low (P<0.02) mean age as compared to squamous cell carcinoma. The difference of mean age in cases of adenocarcinoma approached significant level (0.1> P>0.05) as compared with small cell carcinoma.

INTRODUCTION
Cancers of the lung remain one of the most frequently diagnosed malignant neoplasms throughout the world\(^1\)-\(^4\). In Pakistan, amongst the males, the malignant tumours of the bronchus rank number one\(^5\). Various regional studies also show that malignancies of the lung are a common malignancy of the male in Pakistan\(^6\)-\(^7\).

Development of malignancies of the lung is a multifactorial process. These factors include smoking\(^8\), ionizing radiation, metals, diffuse pulmonary fibrosis\(^9\) and asbestos exposure\(^2\). The age distribution in different malignancies varies in different countries e.g. carcinoma of the breast presents at earlier age in Pakistan as compared with the west\(^10\).

The present study was carried out to see the age and sex distribution of pulmonary malignancies so as to establish the base line data in central Punjab.

MATERIALS AND METHODS
Three hundred patients of primary malignancies of the lung from Gulab Devi Chest Hospital and other hospitals of Lahore were included in this study. Gulab Devi Chest Hospital drains the maximum number of cases of pulmonary malignancies from the region of central Punjab. Patients of all ages and both sexes were included in the study. History of the patients regarding name of patient, age, sex, presenting complaints with duration, etc were recorded. Patients were examined clinically, lymph node enlargement was noted and recorded along with relevant investigations, x-ray chest, bronchoscopy, and CT scan (is available).

The specimens included were bronchial biopsy, transthoracic core needle lung biopsy, open lung biopsy and / or regional lymph node biopsy.

The sections of all the cases were stained with haematoxylin and eosin whereas all large cell carcinomas were stained with Alcian Blue-Periodic Acid-Schiff (AB-PAS) stain\(^11\), without diastase as well as with diastase.

The tumors were classified according to WHO classification\(^12\). Chi square test was used for statistical analysis.

RESULTS
The age ranged from 10-90 years with mean age of 54.17±3.46 years. The maximum number of patients (87.01%) was in the age group 40-79 years (Fig. 1). There were 255 males and 45 females with males to female ratio of 5.7:1.

Squamous cell carcinoma was more common in age groups of 50-79 years (Fig 2). Significantly large numbers of cases (P<0.001) of squamous cell carcinoma were stained with Alcian Blue-periodic Acid-schiff (AB-PAS) stain\(^11\), without diastase as well as with diastase.

The tumors were classified according to WHO classification\(^12\). Chi square test was used for statistical analysis.

The mean age in squamous cell carcinoma cases was significantly less (P<0.05) as compared with adenocarcinoma. The cases in large cell carcinoma group above 40 years were significantly less (P<0.05) as compared with squamous cell carcinoma (Table 1).

Sex and age distribution in different malignancies is given in tables 2 and 3 respectively. Different tumours were significantly more (P<0.001) in males than in females (Table 2).

DISCUSSION
Malignancies of the lung remain one of the most frequently diagnosed malignant neoplasms throughout the world. It is the number one cause of cancer death in American males and females. Bronchogenic carcinoma is being diagnosed with increasing frequency in China, Japan, Canada, and European Countries, as well as in India. Similarly in Pakistan, malignant tumours of the lung ranked number one, among males.

Carcinoma of the lung is generally considered a disease that predominantly affects middle aged and elderly men. In this study of 300 cases of primary lung carcinoma there were 255 males and 45 females with a male to female ratio of 5.7:1. It is in accordance with the study of Jindal, who reported a ratio of 5.2:1 and that of Al-tamimi et al with a ratio of 5.1. However male to female ratio in other studies was 2:1, 2.4:1 and 2.9:1.

Biomedica Vol. 21 (Jan. – Jun., 2005)
The age of patients in this study ranged from 10-90 years with a mean age of 54.7±3.46 years. (Fig. 1). This is in accordance with the study of Srivastava19; he reported a higher mean age, ranging from 61.8 to 71 years18,23,27. Squamous cell carcinoma was more common in age groups of 50-79 years (Fig 2). This is in accordance with a number of published reports with an age range of 55 to 75 years15,17,20.

Significantly large numbers of cases (P<0.001) of squamous cell carcinoma were above 40 years of age as compared with adenocarcinoma. The cases in large cell carcinoma group aging above 40 years were significantly less (P<0.05) as compared with squamous cell carcinoma (Table 1). Moreover different tumours were significantly more (P<0.001) in males than in females (Table 2). Our results are similar to other studies17-20,23.

The mean age in cases of squamous cell carcinoma was significantly high (P<0.001) as compared with adenocarcinoma. The cases of small cell carcinoma had significantly low (P<0.02) mean age as compared with squamous cell carcinoma. The difference in mean age in case of adenocarcinoma approached significant level (0.1>P>0.05) as compared with small cell carcinoma. Similar results were seen in other studies24,28.

As a conclusion this study has highlighted the different aspects of age and sex distribution of primary malignancies of the lung.
